What is Angina (types of angina)?

Angina is chest pain or discomfort resulting from decreased flow of oxygenated blood to the heart. In most cases this lack of blood flow is due to coronary heart disease, which is when the coronary arteries that feed the heart become narrowed. Therefore, angina is technically a symptom and not a disease.¹

The heart requires an adequate blood supply to function properly, and oxygenated blood is fed to the heart through the coronary arteries. If you develop coronary heart disease, fatty deposits called plaques, or atheroma, gradually build up inside these arteries, narrowing them and reducing the amount of blood able to flow through them. When the heart is required to pump more blood than usual, for example during exercise, the narrowed arteries cannot supply the heart with enough oxygenated blood quickly enough, and pain develops.¹
